

ABSTRACT OF THE DISCLOSURE

The objective of the present invention is to suppress uneven densities in an image, and therefore, the present invention provides an image forming

5 apparatus including:

an image bearing member;

a first developing unit, including a first developer carrying member, for developing a first latent image formed on the image bearing member;

10 a second developing unit, having a second developer carrying member, for developing a second latent image formed on the image bearing member after the first developing unit has developed the first latent image;

15 a rotary unit, for holding the first and the second developing units and for moving the first and the second developing unit to positions opposite said image bearing member,

wherein, upon the reception of an image forming
20 signal at the image forming apparatus, the first and the second bearing members are rotated before the first latent image on the image bearing member is developed.
